Alcovia: Product, Systems & Analytics Lead assignment

GTM tracker (live) | Student tracker (live) | GitHub repo

The short version

1. **Problems 1 and 4 have the same fix.** The daily rigour (timetable, 8pm quiz, focus time, chapter progress) lives in docs, folders and ClickUp today. If it moves into the app, students get a reason to open it every day, and the student dashboard fills itself. So I'd run the app-adoption work and the student-dashboard work as one project, not two.
2. **Make "30 minutes" mean 30 minutes of focus, not screen time.** No parent wants their teen on a phone for longer. One 25-minute locked Focus session a day, plus the quiz and a day plan, gets a student to about 30 minutes, and every one of those minutes is time parents are glad about.
3. **Ship the GTM tracker first (live by 20 Nov).** The data already exists in Meta, ClickUp and Razorpay, and it makes revenue accountable from week 3. The one thing to fix first is a lead ID that travels from the ad to the payment. Without it, nobody can say which campaign produced revenue, only which produced leads.
4. **Every feature or system goes through one loop:** a one-page Bet Card with a metric, target and kill rule; tracking built before the feature; a 1-week pilot with one pod; and a readout on day 14 that decides scale, iterate or kill. Each step has an owner and a document. This is how I'd keep the success rate high with a team of three.

---

0. How I'd use the team and the first 8 weeks

Who does what

Person	Owns	Does not own
Full stack engineer	App changes (Focus Mode, in-app quiz, day plan, chapter stages), event tracking, wearable sync, Supabase, dashboard pages	Deciding what to build. Every ticket comes with a Bet Card and the events it needs to fire
Process / systems designer (commerce)	ClickUp clean-up (one Leads list, statuses = funnel stages, required fields), Razorpay links, invoices and renewals, n8n workflows, advisor input forms, SOPs and data hygiene	App code
Me	Problem framing, metric definitions, Bet Cards, talking to teens, parents and advisors, dashboard design, analysis, weekly reviews, QA on every release, and saying no	Being the only person who knows how a system works. Everything I set up gets a runbook

Timebox: join 1 Nov (Sun), week 1 starts Mon 2 Nov

Week	Me	Engineer	Systems designer	Visible output
W1 2–8 Nov	Talk to 10 students, 5 parents and every advisor. Sit in 3 discovery calls and 1 weekly review. Write the metric dictionary.	Audit app event tracking. Set up Supabase. Start sending app events.	Audit ClickUp: map each status to a funnel stage, list the missing fields.	Metric dictionary signed off. Adoption baseline confirmed

W2–W3 9–22 Nov	GTM tracker v1 design and QA. Bet Cards for the daily loop.	Day plan and in-app 8pm quiz (pilot pod)	ClickUp → Supabase sync. Razorpay webhook. Meta Ads daily pull. Lead ID in Razorpay notes.	**GTM tracker live 20 Nov.** First Monday GTM review on 23 Nov
W4–W5 23 Nov–6 Dec	Pilot readouts. Student dashboard KPI sign-off with advisors.	Focus Mode v2 (phone lock + whitelisted calls). Realm rewards tied to focus. Apple Health / Health Connect sync.	Advisor weekly input form. Session check-in + 2-tap rating. Alert rules.	Daily loop live for all students. Day-14 readout
W6–W7 7–20 Dec	Student dashboard v1 QA. Parent weekly summary.	Chapter stages in app. Advisor dashboard page.	Nightly roll-up and alerts. Weekly advisor digest.	**Student dashboard live 18 Dec.** Weekly review runs off it
W8 21–27 Dec	Month-2 review: what worked, what to kill, Q1 bets	Fixes and hardening	Runbooks and error alerts on every workflow	Q1 plan, decisions log

Order of work: GTM first because the data exists and it pays for itself. The daily loop starts in week 2 because the adoption numbers and the student dashboard both depend on it. Problem 3's process runs from day one.

---

1. App adoption: 2.15 → 30 minutes a day

What the numbers say

- **The game works and study doesn't.** Home and the Realm are used. The Focus Timer has 11 who tried it but only 5 regulars. Syllabus dropped from 10 students to 1, and nobody opened the Study Planner this week. Students come for the fun parts and leave before the parts that matter to us.
- **25 features for 20 students is too much to think about.** A 14-year-old opening the app has to choose between Home, the Realm, Dragons, Coins, Streak, Rankings, Side Quests, Syllabus, Planner, Goals, Wellness… Most of these got one try.
- **Wellness depends on hardware most students don't have.** One student connected WHOOP. Most teens have an Apple Watch, a Samsung watch or nothing.
- **An average of 20 users is fragile.** Two heavy Realm players can move it a lot. I'd track the median and the share of students who did the core action, not only the mean.

What I'd change the goal to

"30 minutes in the app" should mean "30 minutes of the app doing its job". The metric I'd make the north star is **focus minutes per active Alcovian per day**. It measures app usage and study effort at the same time, and it is screen time a parent is happy to see. Two supporting metrics: **% of students who finish the daily loop** (plan, focus, quiz), and **7-day return rate**.

The plan: one daily loop instead of 25 features

Step	Time	What changes
1. Plan my day	~2 min	After school, the app shows today's timetable blocks (tuition, sports, free time) and suggests 1–2 self-study blocks on chapters that are behind pace. One tap to accept.
2. Focus	25–50 min	Starts from the planned block. The phone locks except for whitelisted calls (parents). Focus minutes are the *only* way to win Realm territory and hatch dragons. Daily login coins drop. The game the students already like now pays for the study habit.

3. 8pm quiz	~5 min	Moves into the app with a push at 7:55pm, a pod leaderboard and streaks. It's an existing daily habit; we just move it to where the other data is.
4. Check-in	~1 min	Mark chapter stage, rate today, see "my week". This feeds the student dashboard without anyone typing in ClickUp.

- **Hide, don't delete.** Rankings, Side Quests, Goals and wellness extras move behind Discover until the loop works. Home becomes "your next step", not a feed of 9 cards.
- **Make it social.** Pod focus rooms (5 Alcovians focusing at the same time) and a weekly pod focus goal. Pods already exist offline; this uses them.
- **Pull from advisors and parents.** The weekly advisor review runs off the app's data, so advisors ask students to log. Parents get a Sunday summary ("Aanya focused 3h 40m this week"), so parents ask for it too.
- **Wellness with no effort.** Read from Apple Health and Health Connect (Samsung, Garmin and others sync into these), plus WHOOP for students who have one. No new device needed.

Targets and how I'd test with 20 students

Ramp: **10 min by end of Dec → 20 by end of Feb → 30 by end of Mar.** With 20 users, A/B tests won't reach significance. Instead I'd roll out pod by pod: one pod gets a change for a week, then compare against the other pods and against that pod's own previous week. I'd also watch 3 students use the app on a screen share for every release. With this few users, 3 live sessions teach more than a dashboard.

Guardrail: if focus minutes rise but quiz scores, chapter readiness or sleep drop, we're pushing too hard. Those are on the student dashboard for exactly this reason.

---

2. GTM tracker

Live prototype: https://alcovia-ops.vercel.app/gtm.html (dummy data, every number recalculates for the timeline you pick).

Ask in the brief	Where it is on the tracker	Source
Revenue target vs achievement, trial vs full, students onboarded, workshop revenue (₹3,999/seat), program vs workshop, unpaid invoices, trial renewals due	KPI row, weekly revenue chart with cumulative target line, split doughnut, unpaid invoices with ageing, renewals table with an engagement signal	Razorpay webhook, enrollments, monthly targets
Funnel: leads → qualified → discovery set (show-up) → ambition interview (drop-off) → architect session → signed	Funnel with step conversion, show-up rate and drop-off, filter by source	ClickUp status changes, timestamped per stage
CPQL, program conversion %, organic leads, average lead journey	Top-metrics strip, journey days split by signed vs dropped	Meta spend + leads
Campaign performance, CTR best/worst, frequency 3+, landing page health	Creative table with SCALE / HOLD / REFRESH / KILL badges; landing page table (drop-off, load time over 3s flagged)	Meta Ads API daily pull, site analytics
RCA: what to drop, refresh, scale	Bubble chart (cost per qualified lead vs conversion, size = spend) plus an auto-written "calls for this period" list	All of the above, joined by lead ID

Three things that make it trustworthy

1. **One lead ID from ad to payment.** Meta lead form → ClickUp task → Razorpay payment link notes all carry the same lead ID. This is the only way to judge a creative by the revenue it brought in, not the leads.

2. **ClickUp statuses are the funnel.** One Leads list, one status per stage, and an n8n timestamp whenever a status changes. Nobody fills in the tracker by hand. Smallest.ai reminder calls are triggered when the status moves to "Discovery set", so the show-up rate is something we act on, not just report.
3. **Rules, not opinions, for RCA.** Refresh if 7-day frequency is 3 or more or CTR is in the bottom quarter. Scale if CPQL is 20% or more below the campaign median and the creative has converted. Kill if spend passes 2× median CPQL with no qualified lead. We review the rules monthly; the tracker applies them daily.

Cadence: a 30-minute Monday GTM review using only the tracker. Each red number gets one owner and one action, logged in ClickUp.

---

3. A structure that makes features and systems succeed

Most features fail for one of three reasons: nobody agreed what success means, nobody can measure it after launch, or it adds steps for a teen who has no reason to take them. The process below targets those three. It's the same for an app feature, a new dashboard or an n8n automation.

Step	Owner	Document	The step is done when
1. Frame	Me	*Bet Card* (1 page): problem, who it's for (teen / parent / advisor), evidence, one success metric with baseline → target → date, one guardrail metric, kill rule, cognitive-load budget	The founder agrees with the metric and the kill rule. If we can't name the metric, we don't build it
2. Shape	Me + systems designer	Flow sketch, the events it must fire, manual steps it removes or adds, who does what	30-minute review. The engineer can estimate it. Event names are added to the metric dictionary
3. Build	Engineer	ClickUp tickets	Done = works on the test account, events show up in Supabase, the dashboard tile exists, it's behind a flag
4. Pilot	Me	Pilot notes	One pod for one week. I watch 3 students use it live. Bugs fixed
5. Launch	Systems designer	3-line SOP for advisors, parent note if needed	Everyone affected knows what changed and what they need to do
6. Readout	Me	Day-14 and day-30 readout in the decisions log	Decision made: **scale**, **iterate once**, or **kill**. A missed target with no decision is not allowed

The cognitive-load budget (written on every Bet Card)

- A teen can do the core action in **3 taps and under 10 seconds**, with no explanation.
- At most **1 new screen**. If something is added, something else gets hidden.
- A parent understands any summary we send in **5 seconds**.
- An advisor's manual input stays **under 10 minutes per student per week**.

Rhythm for a team of three

- **Monday (30 min):** GTM review, then plan the week in ClickUp. At most 2 bets in build at once.
- **Daily:** a written check-in in ClickUp (yesterday, today, blocked). No standing meeting.
- **Thursday:** 20-minute demo of anything shipped or piloted.
- **Every other Friday:** readouts and the decisions log.

Systems that don't break

- Every n8n workflow has an owner, writes a row to `ingest_log` on each run, retries on failure, and alerts ClickUp on error. Upserts are keyed on source IDs, so a re-run never duplicates data.
- A weekly data-quality check flags leads missing a stage date, payments with no lead ID, and students with no app event in 7 days.
- Every system has a one-page runbook, so any of the three of us can fix it.

---

4. Student dashboard

Live prototype: https://alcovia-ops.vercel.app/students.html (dummy data, filter by timeline, pod and advisor; click a student to drill down).

KPIs through the three lenses

Level / activity	Quantity: did Alcovia conduct it?	Quality: did Alcovians like it?	Performance: how did the Alcovian do?
Daily: timetable, quiz, focus, active minutes, recovery	Quiz held on % of days; % of students with a day plan	Quiz participation %; streak retention	Timetable adherence %, quiz score %, focus minutes/day, active minutes, sleep hours, recovery %
Weekly: academic sessions, academic roadmap	Sessions held vs scheduled; roadmap reviewed on time	Attendance %, session rating	Task completion, deadline adherence, time-estimate accuracy, chapter readiness score, syllabus pace vs 25% per quarter, exam score vs target
Monthly: workshops, pod, peer, mentor call, personal branding	Held vs planned, per type	Attendance, rating, % would recommend	Soft-skill scores from workshops (teamwork, adaptability, public speaking…); branding clips posted
Quarterly: podcast, competition prep, parent-child, out of city, theme	Held vs planned	Student and parent rating	Competition result, theme project milestone done
Roadmaps: career, personal, academic	Roadmap exists and was reviewed this month	Student agrees with it (1 question)	Career: done / not done. Personal: monthly milestones hit %. Academic: readiness + syllabus pace

The advisor's job, given they aren't subject experts

The advisor doesn't need to teach chemistry. Their job is process: set targets from subject affinity and past scores, protect self-study time in the timetable, and check that each chapter goes through every stage of rigour (read → notes → practice ≥70% → timed past paper → ready ≥80%). When a subject falls a set percentage behind target, an alert brings in a tutor. The dashboard holds advisors to these process metrics, which they control, not to marks, which they don't.

How data gets in without manual work

Data	How it's captured	Human effort
Focus minutes, app usage, day plan, quiz, chapter stage, tasks	App events → Supabase	None (the student does it as part of using the app)
Active minutes, sleep, recovery	Apple Health / Health Connect / WHOOP sync	One-time permission
Attendance and rating for any session	QR / one-tap check-in, then a 2-tap rating push after the session	2 taps

Practice accuracy, exam results	Student enters it in the app; advisor verifies in the weekly form	About 5 minutes a week
Advisor notes, roadmap status, soft-skill scores	One structured ClickUp form per student per week → n8n → Supabase	Under 10 minutes per student per week
Payments, renewals	Razorpay webhook	None

Where it shows up

- **Advisors and founders:** a web dashboard (the prototype) with a cohort table sorted by "needs attention" and a per-student drill-down. It replaces the weekly doc.
- **Students:** a "My week" card on Home.
- **Parents:** a Sunday WhatsApp summary and a monthly report. Instant alerts only for a missed deadline or a subject falling behind pace.

Timeline: KPI sign-off by 4 Dec, data flowing by 11 Dec, dashboard v1 live on 18 Dec, weekly reviews run on it from the first week of January.

What's in the repo

- `dashboard/` : both dashboards (static HTML/JS, dummy data generated in the browser so filters really work)
- `sql/` : Postgres/Supabase schema, views, and one metric query per dashboard tile
- `n8n/` : importable workflows: ClickUp lead-stage sync (+ Smallest.ai reminders), Razorpay webhook, Meta Ads daily pull with creative alerts, nightly student roll-up and alerts, weekly advisor digest, and an error-alert workflow the others report failures to. The creative flags and student alert rules each live in one SQL function, so the dashboard and the alerts can never disagree

Assumptions

- Usage numbers come from the brief; I haven't seen raw event data. Week 1 starts by confirming the baseline.
- The 8pm quiz and the timetable currently run outside the app.
- Supabase (Postgres) is used as the store because it's cheap, works well with n8n and the app, and lets a non-engineer read the SQL. Any Postgres would do.
